## **1. Experiment section**

### **1.1 Chemicals**

Poly(vinylpyrrolidone) (PVP,  $M_w=1300000$  g mol<sup>-1</sup>) was purchased from Thermo Scientific, indium nitrate hydrate ( $\text{In}(\text{NO}_3)_3 \cdot 4.5\text{H}_2\text{O}$ ) and cobalt nitrate hexahydrate ( $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ ) were provided by Aladdin Chemistry Co., Ltd. Nafion solution was acquired from Shanghai Hesen Electric Co., Ltd. N,N-dimethylformamide (DMF) and ethanol were available from Sinopharm Chemical Reagent Co., Ltd.

### **1.2 Preparation of Co/In<sub>2</sub>O<sub>3</sub>**

Firstly, of 0.239 g  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ , 0.261 g of  $\text{In}(\text{NO}_3)_3 \cdot 4.5\text{H}_2\text{O}$  and 0.5 g of PVP were added into a mixture system consisting of 2.5 mL of ethanol and 2.5 mL of DMF to produce a uniformly mixed precursor solution. Then, the  $\text{Co}(\text{NO}_3)_2/\text{In}(\text{NO}_3)_3/\text{PVP}$  precursor was adopted for electrospinning under a voltage of 18 kV. Next, the precursor was heated to 450 °C in air with a heating rate of 2 °C for 2 h. Finally, after cooling to the room temperature, the collected product was named as  $\text{Co}_3\text{O}_4/\text{In}_2\text{O}_3-1$  fibers. Subsequently, the obtained oxide fibers were placed in a tube furnace and reduced at 400°C with a heating rate of 2 °C for 4 h in a  $\text{H}_2/\text{Ar}$  atmosphere to obtain the product  $\text{Co}/\text{In}_2\text{O}_3-1$ . By contrast, the synthesis procedures for the preparation of other control samples are consistent with that to obtain  $\text{Co}/\text{In}_2\text{O}_3$ . Specifically,  $\text{Co}/\text{In}_2\text{O}_3-0.5$  was obtained by varying the added amounts of 0.157 g of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and 0.343 g of  $\text{In}(\text{NO}_3)_3 \cdot 4.5\text{H}_2\text{O}$ .  $\text{Co}/\text{In}_2\text{O}_3-2$  was obtained by varying the added amounts of 0.323 g of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and 0.177 g of  $\text{In}(\text{NO}_3)_3 \cdot 4.5\text{H}_2\text{O}$ . Co was obtained by varying the added amounts of 0.5 g of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ , and  $\text{In}_2\text{O}_3$  was obtained by varying the added amounts of 0.5 g of  $\text{In}(\text{NO}_3)_3 \cdot 4.5\text{H}_2\text{O}$ . The obtained  $\text{In}_2\text{O}_3$  sample after  $\text{H}_2/\text{Ar}$  reduction treatment is defined as  $\text{In}_2\text{O}_3\text{-H}$ .

### **1.3 Electrochemical measurement**

Electrochemical measurements were conducted using CHI 660E electrochemical workstation within an H-type electrolytic cell. Hg/HgO electrode was used as the reference electrode and Pt wire was used as counter electrode. The working electrode was prepared as follows: 4 mg of sample was dispersed in 980  $\mu\text{L}$  ethanol and 20  $\mu\text{L}$  Nafion mixture solution to form a uniform catalyst ink. Then, a certain amount of ink

was dropped on the surface of a carbon cloth electrode to attain a mass loading of  $1 \text{ mg cm}^{-2}$ . The anode and cathode chambers were filled with  $1.0 \text{ M KOH}$  solution ( $30 \text{ mL}$ ), followed by the introduction of  $0.1 \text{ M KNO}_3$  into the cathode chamber for nitrate reduction testing. LSV curves were generated until a stable state occurred with a potential range from  $-0.6$  to  $-1.8 \text{ V}$  relative to  $\text{Hg/HgO}$ . Unless otherwise specified, all the potentials are corrected relative to reversible hydrogen electrodes (RHE) (Figure S24,  $E_{\text{RHE}}=E_{\text{Hg/HgO}}+0.93 \text{ V}$ ). Chronoamperometric tests were conducted at different potentials for  $1 \text{ h}$ . The cycling stability test was conducted by filling the anode and cathode chambers with  $1.0 \text{ M KOH}$  solution ( $100 \text{ mL}$ ), and then introducing  $0.1 \text{ M KNO}_3$  into the cathode chamber for nitrate reduction testing. The Mott–Schottky curve test was carried out in a three electrode system, with platinum wire as the counter electrode and  $\text{Ag/AgCl}$  as the reference electrode.  $\text{In}_2\text{O}_3\text{-H}$  loaded on a glassy carbon electrode with a loading amount of  $1 \text{ mg cm}^{-2}$  was used as a working electrode and the electrolyte is  $0.5 \text{ M NaSO}_4$ . The aqueous  $\text{Zn-NO}_3^-$  battery was assembled using  $\text{Co/In}_2\text{O}_3\text{-1}$  ( $1 \times 1 \text{ cm}^2$ ,  $1 \text{ mg cm}^{-2}$ ) as the cathode and  $\text{Zn}$  foil ( $1 \times 1 \text{ cm}^2$ ) as the anode,  $30 \text{ mL}$  of  $1 \text{ M KOH}$  with  $0.1 \text{ M KNO}_3$  as the cathode electrolyte, and  $30 \text{ mL}$  of  $3 \text{ M KOH}$  as the anode electrolyte.

#### **1.4 Material Characterization**

Field emission scanning electron microscopy (FESEM) was constructed using a FEI Nova NanoSEM and FEI Thermo measurement. Transmission electron microscopy (TEM) was conducted by JEM-2100 F, JEOL and high-resolution TEM (HRTEM, FEI Tecnai G2 F20). High-resolution transmission electron microscopy (HRTEM), elemental mapping and energy dispersive X-ray (EDX) spectroscopy were obtained by using a FEI Tecnai G2 F20 electron microscope. Inductively coupled plasma-optical emission spectrometry (ICP-OES) were using Agilent 725. X-ray photoelectron spectra (XPS) analysis was performed on Thermo Scientific Nexsa measurement. X-ray diffraction (XRD) patterns were obtained by PANalytical B.V and Rigaku DESKTOP. The model of the Fourier Transform Infrared (FTIR) spectrometer (Bruker) testing instrument is VECTOR22. Avance NEO NMR spectrometer ( $400 \text{ MHz}$ ) was employed to ascertain the origin of ammonia. Ultraviolet-visible diffuse reflectance spectra (UV-

vis DRS) were carried out through PerkinElmer Lambda 850, with BaSO<sub>4</sub> as a reference.

### **1.5 Determination of ion concentration.**

The ultraviolet-visible (UV-vis) spectrophotometer was carried out to measure the ion concentration of the electrolyte following the test.

#### **1.5.1 NO<sub>3</sub>-N**

A certain amount of electrolyte was removed from our electrolytic cell and diluted to a convenient 4 mL. Subsequently, 0.08 mL of 1 M HCl and 0.008 mL of 0.8 wt% amino sulfonic acid solution were added into the above solution. An UV-vis spectrophotometer was then employed to observe the absorption spectrum. This was followed by generating a calibration curve of absorbance concentration using several standard potassium nitrate solutions.

#### **1.5.2 NO<sub>2</sub>-N**

An aqueous system consisting of *p*-aminobenzenesulfonamide (4 g), N-(1-Naphthyl) ethylenediamine dihydrochloride (0.2 g), ultrapure water (50 mL) and phosphoric acid (10 mL,  $\rho=1.70 \text{ g mL}^{-1}$ ) was employed as a colorimetric reagent. An amount of the electrolyte was diluted to 4 mL, then 0.1 mL of the afore-mentioned colorimetric reagent was added to the above solution and gently mixed. An UV-vis spectrophotometer was utilized to assess the absorption spectrum. The absorbance-concentration curve was calibrated using a series of standard potassium nitrite solutions.

#### **1.5.3 NH<sub>3</sub>-N**

An amount of the electrolyte was diluted to 4 mL, then 0.1 mL of potassium sodium tartrate solution ( $\rho=500 \text{ g L}^{-1}$ ) was added to above solution. In the following, 0.1 mL of Nessler's reagent was injected into the mixture. A UV-vis spectrophotometer was utilized to provide the absorption spectrum. The absorbance-concentration curve was calibrated using a series of standard ammonium chloride solutions.

### **1.6 Isotope Labeling Experiments**

1 M KOH and 0.1 M K<sup>15</sup>NO<sub>3</sub> solution were employed as electrolyte. Following 1 h chronoamperometry test at -0.8 V vs. RHE, the electrolyte was removed and mixed with 0.08 mL of hexadeuterodimethyl sulfoxide (DMSO-d<sub>6</sub>) and 0.08 wt% of Maleic acid (C<sub>4</sub>H<sub>4</sub>O<sub>4</sub>) for <sup>1</sup>H NMR (400 MHz) testing.

## 1.7 Calculation of the NH<sub>3</sub> yield rate and Faradaic efficiency

The NH<sub>3</sub> yield rate is calculated by the Eq. 1

$$\text{Yield rate}_{\text{NH}_3} = \frac{c_{\text{NH}_3} \times V}{M_{\text{NH}_3} \times t \times S}$$

The NH<sub>3</sub> Faradaic efficiency is calculated by the Eq. 2:

$$\text{Faradaic efficiency}_{\text{NH}_3} = \frac{8 \times F \times c_{\text{NH}_3} \times V}{M_{\text{NH}_3} \times Q}$$

where  $c_{\text{NH}_3}$  is the mass concentration of NH<sub>3</sub> (aq),  $V$  is the volume of electrolyte in the cathode compartment (30 mL or 100 mL),  $M_{\text{NH}_3}$  is the molar mass of NH<sub>3</sub>,  $t$  is the electrolysis time (1 h),  $S$  is the geometric area of working electrode (0.2 cm<sup>2</sup>),  $c$  is the generated concentration of ammonia,  $F$  is the Faradaic constant (96485 C mol<sup>-1</sup>),  $Q$  is the total charge passing the electrode.

## 2. Computational methods

Vienna Ab initio Simulation Package (VASP) was used to carry out the spin-polarized density functional theory (DFT) calculation.<sup>1</sup> The generalized gradient approximation (GGA) with Perdew-Burke-Ernzerhof (PBE) exchange-correlation functional was carried out for electron correlation.<sup>2</sup> The valence electron wave functions were expanded in a plane wave basis set with an energy cutoff of 400 eV, and the core electrons were represented by the projector augmented-wave (PAW) method.<sup>3</sup> For geometry optimization, a 3×3×1 k-point grid was used, while electronic structure calculations was opted for a denser 5×5×1 grid, both following the Monkhorst-Pack scheme. The force and energy convergence criteria were set to 0.05 eV/Å and 10<sup>-5</sup> eV. A Van der Waals correction was applied using the DFT-D3 method.<sup>4</sup> For pristine Co and the In<sub>2</sub>O<sub>3</sub>, (111) surface for Co and (211) surface for In<sub>2</sub>O<sub>3</sub> were chosen, and three-layer slabs were constructed with 2×2 surface unit cells. To model the Co/In<sub>2</sub>O<sub>3</sub> structure, a Co cluster consisting of 26 atoms was gently attached to the In<sub>2</sub>O<sub>3</sub> (211) surface. All the slabs were separated by a 15 Å vacuum space in the Z-direction to avoid periodic interactions. The corresponding reaction free energies ( $\Delta G$ ) were calculated using the computational hydrogen electrode (CHE) model:<sup>5</sup>

$$\Delta G = \Delta E + \Delta ZPE - T\Delta S$$

where  $\Delta E$  is the energy difference between the products and reactants,  $\Delta ZPE$  is the zero-

point energy correction, and  $T\Delta S$  is the entropy change.
