General experimental information

General procedures.

All reagents were purchased and used as received except when indicated. Chemical shifts (δ) are given in ppm downfield from Me₄Si and refer to the internal standard to the residual solvent (unless indicated) CDCl₃: (δ = 7.26 for ¹H and 77.00 for ¹³C). The coupling constants, J , are reported in Hertz (Hz). TLC was carried out on SiO₂, and the spots were located with UV light. Flash chromatography was carried out on SiO₂. The organic extracts were dried over anhydrous Na₂SO₄ during the reactions. Evaporation of the solvents was accomplished with a rotatory evaporator.

Caution for high temperature reactions.

We urge researchers to be careful when conducting any high temperature experiments and ensure that special precautions be taken. Glass capillaries can explode at high pressures and temperatures, producing dangerous sharp fragments. The necessary precautions should be taken and appropriately configured laboratory environment should be arranged.

Computational details.

Geometry optimization for pyrazoles and vibrational frequency calculations were performed via the PBE1PBE (PBE0)^{1,2} hybrid functional and def2TZVP^{3,4} basis set, the D3 version of Grimme's dispersion with Becke–Johnson damping (GD3BJ)^{5,6} in Gaussian16⁷. The SMD model (solvation model based on the charge density of solute molecules) was used as a continuum model of the solvent (*p*-xylene) media.⁸ For all the structures, the thermodynamic parameters were calculated at 298.15 K and 1 atm. For all structures the calculations were also carried out at 773 K and 35 atm. This temperature and pressure are approximately the same as the conditions for synthesis. Stationary points were characterized as minima by evaluating the elements of the Hessian matrix. All the observed transition states had one negative vibrational mode corresponding to the reaction path. Visualization and analysis of optimized structures were performed using CYLview program.⁹

ESI-HRMS study.

The samples for the ESI-TOF-HRMS experiments were prepared in 1.8 mL glass vials with screwtop caps fitted with Teflon-lined septa (Agilent Technologies). High-resolution mass spectra (HRMS) were recorded on a Bruker maXis q-TOF (tandem quadrupole/time-of-flight mass analyzer) mass spectrometer equipped with an electrospray ionization (ESI) source. The *m/z* scanning range was 50–3000. The measurements were carried out in positive ion mode (+) (ground spray needle, -4500 V high-voltage capillary; 500 V HV end plate) and in negative ion mode (-) (ground spray needle, +4000 V high-voltage capillary; -500 V HV end plate offset). External calibration of the mass scale was carried out via the low-concentration calibration solution “tuning mix” (Agilent Technologies). The samples were injected via a 500 μ L Hamilton RN 1750 syringe (Switzerland). The flow rate during injection was controlled with a syringe pump (3 μ L/min).

Nitrogen was used as the nebulizer gas (1.0 bar) and dry gas (4.0 L/min, 200 °C). The data were processed via Bruker Data Analysis 4.0 software.

NMR study.

NMR spectra were recorded via Bruker Fourier 300HD spectrometers operating at 300.1 MHz for ¹H and 76 MHz for ¹³C. The ¹H and ¹³C NMR chemical shifts are reported relative to the solvent signals as internal standards: 2.50 ppm/39.5 ppm for DMSO-*d*₆ and 7.26 ppm/77.2 ppm for CDCl₃. All the measurements were performed at room temperature.

X-ray crystallographic data and refinement details.

X-ray diffraction data were collected at 100 K on a four-circle Rigaku Synergy S diffractometer equipped with a HyPix6000HE area detector (kappa geometry, shutterless ω -scan technique) using graphite monochromatized Cu K_a-radiation. The intensity data were integrated and corrected for absorption and decay via the CrysAlisPro program¹⁰. The structure was solved via direct methods via SHELXT¹¹ and refined on F^2 via SHELXL-2018¹² in the OLEX2 program.¹³ All nonhydrogen atoms were refined with individual anisotropic displacement parameters. All hydrogen atoms were placed in ideal calculated positions and refined as riding atoms with relatively isotropic displacement parameters. The Mercury program suite¹⁴ was used for molecular graphics. The structures have been deposited at the Cambridge Crystallographic Data Center with the reference CCDC numbers 2419386.

GC-MC analysis.

The system consists of a gas chromatograph (Agilent Technologies 7890B) coupled with a quadrupole mass spectrometer equipped with an electron ionization source (Agilent Technologies 5977A MSD). NIST 2017 mass spectral library software, version 2.3 (Gaiticsburg, Pennsylvania, USA), was used to collect and process the data.

GC-MS analysis was performed on a HP Agilent 5 ms capillary column with a length of 30 m, an I.D. of 0.25 mm, and df of 0.25 μ m, carrier gas - helium, injector temperature - 270 °C, initial chromatograph oven temperature - 60 °C, heating rate 10 °C/min to 300 °C, followed by isotherm for 5 min; MS parameters: electron ionization at 70 eV, source temperature - 230 °C.

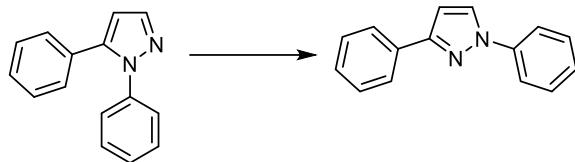

Sample preparation for GC/MS analysis. Two microliters of the upper reaction layer was transferred to a vial and diluted with 1 ml of ACN (HPLC). A 1 μ l solution was injected into the GC/MS system.

TGA analysis.

Instrument used for TGA analysis - DTG-60H "Shimadzu", heating rate 10 °C/min, temperature range 30–450 (850) °C

Synthetic method

We strongly recommend following corresponding safety procedures. When heated, capillaries may explode with a loud bang.

Capillary preparation method (HTCS):

Pasteur pipettes made of chemical glass (Borosilikatglas 5.1 230 mm Duran) were used in the manufacture of capillaries. The capillary was sealed from the thin part with a burner flame (pencil torch). The samples were then filled with a solution of the substance and sealed. In the synthesis of several tens of milligrams, several tens of capillaries were produced. Capillaries were placed in a vertical state in an aluminum thermoblock. Then, the samples were placed in a heating element. For induction heating, a graphite glass inside the induction heater was used. Otherwise, the samples were placed in a muffle furnace.

One should pay attention to the quality of the sealant, since this greatly affects the course of the experiment. Capillaries in which carbon soot had already formed due to the evaporation of solvent vapor and subsequent contact with the hot part of the glass were prone to rupture when heated to 500 °C. This is explained by the large defectiveness of glass at the sealing site due to the emergence of a new phase, such as amorphous carbon, during carbonization of the solvent at the junction, which significantly reduces the quality of this capillary. Another limiting factor in the use of chemical glass capillaries is the maximum synthesis temperature. Capillaries made of chemical glass begin to melt at approximately 700 °C. To overcome this limitation, quartz glass can be used, which increases the synthesis temperature to 1100–1200 °C. Quartz glass has fewer imperfections and a coefficient of thermal expansion, which allows syntheses to be carried out with greater internal pressure inside the capillary than when chemical glass is used.

Figure S1. Muffle furnace “satellite” Russia. Maximum heating temperature: 1200 °C.

Measurement of pressure inside the reaction medium:

In a vertical steel reactor with a volume of 60 mL, 15 mL of toluene was added. The reaction medium was purged with argon. The initial pressure was 1 atm. The reactor was then closed with an output to the monometer. The reactor was heated to 500 °C; after the set temperature was established after 10 minutes of heating, the pressure was measured. The pressure at the time of heating increased monotonically, and the highest recorded value was 32.3 bar. The reactor then cooled. After the experiment, the volume of the solution did not change.

Figure S2. Photo of a steel reactor pressure gauge heated to 500 °C.

Induction furnace for syntheses:

The induction heating board module (China, 1000 W, voltage 12-48 V) and power unit (China, CHUX S-1000-24, DC input 20-28 V 40 A) were used. Changing the voltage at the output of the power supply allows the temperature to be adjusted. The capillary was placed vertically inside an aluminum block, which was located in a craft glass. The graphite glass is located inside the inductor. Temperature measurements were carried out on the outer part of the aluminum block with a pyrometer (“KELVIN KB DIPOLE PYROCELSUS” Russia).

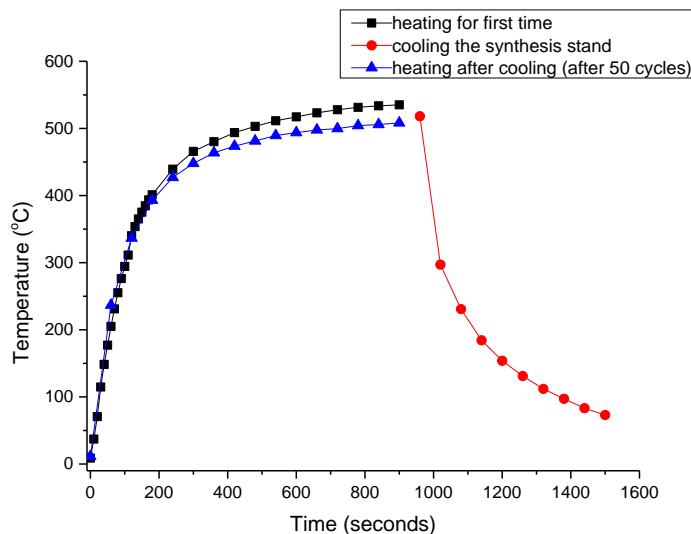

Figure S4. Induction heating operating mode.

Influence of inert gas on the reaction:

The capillary, which is sealed on one side, is filled with the prepared mixture of 1,5-diphenylpyrazole in *p*-xylene. After that, the capillary is purged with argon via a gas ball with an outlet in the form of a syringe for 10–15 seconds. After that, the capillary was sealed. The capillary was then placed in a heating cassette and placed in a muffle furnace heated to the desired temperature.

There are no differences in the course of the reaction depending on the gas atmosphere that fills the capillary. There was no difference in the GC–MS data between the samples filled with argon and those filled with air. This is most likely due to the small amount of gas that is present in the capillary, which does not have a significant effect on the course of the reaction.

Catalyst search

The capillary was filled with a solution of 25 µL of *p*-xylene in which 3 mg of 1,5-diphenylpyrazole was dissolved. A total of 0.5 mg of the substance being tested for catalytic activity was added to the capillary. The capillary was subsequently placed in an oven at 500 °C for 3 minutes. A reference capillary was placed in the oven together with a capillary with a substance being tested for catalytic activity without introducing the substance. After synthesis, the capillary was opened on both sides, and the contents were transferred into a vial, where 600 µL of acetone-*d*₆ was added. After stirring, the mixture was transferred to an NMR tube.

Preparation of pyrazoles and isomerization reactions

Synthesis of enaminones. General procedure:

DMFDA (6.5 mmol) was added to a solution of acetophenone (5 mmol) in dry toluene (4 mL) under argon. The reaction mixture was heated to 110 °C until TLC was complete (2 days). After cooling, the solvent was evaporated under reduced pressure, and the resulting residue was purified via crystallization.¹⁵

Synthesis of pyrazoles (1a, 2a, 3a). General procedure:

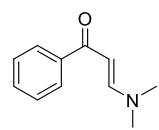

Hydrazine hydrochloride (1 mmol) was added to a mixture of enaminoketone (0.9 mmol) and Na₂CO₃ (0.6 mmol) in MeOH (10 mL) and H₂O (2 mL) under stirring at room temperature. The resulting mixture was acidified with glacial acetic acid to pH 4 and heated to 135 °C for 2 hours. After cooling, the suspension was diluted with EtOAc (30 mL), the organic layer was washed with H₂O (3 × 10 mL), and the solvent was evaporated under reduced pressure. The resulting residue was purified via chromatography on a silica gel with EtOAc/hexane as the eluent.^{16,17}

Synthesis of isomerization pyrazoles (1b, 2b, 3b, 4b, 5b, 6b). General procedure:

Isomerization was carried out according to a previously described procedure (HTCS). The capillary with the substance in the p-xylene solution was sealed on both sides. The reaction was carried out at 500 °C for 5 minutes. After cooling, the capillaries broke. The suspension was diluted with EtOAc (30 mL), the organic layer was washed with H₂O (3 × 10 mL), and the solvent was evaporated under reduced pressure. The resulting residue was purified via chromatography on a silica gel with EtOAc/hexane as the eluent.
