	10	98.45	78.7	69.1	70	1200	

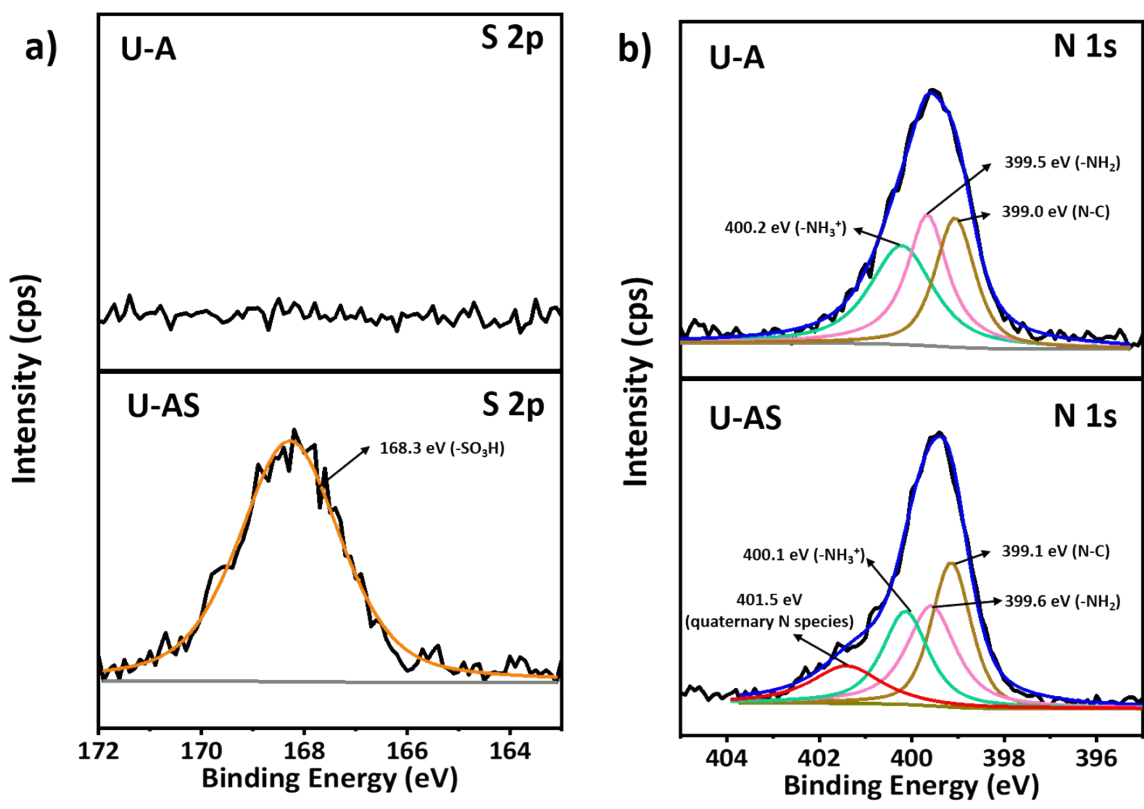

**Fig. S1** The XRD results of (a) UiO-66, U-A and U-AS, and (b) Miller indices of U-A and U-AS.

**Fig. S2** SEM images of (a) U-A as-synthesized and (b) U-AS as-synthesized. (c) FT-IR results of U-A and U-AS. (d) TGA curves of UiO-66, U-A and U-AS.

Due to the functional groups, U-A and U-AS showed significantly different thermal decomposition behavior from UiO-66 in Fig. S2d. In addition, U-A and U-AS showed a similar trend in TGA results. The adsorbed volatile molecules were evaporated up to about 200 °C. The U-A and U-AS showed more weight loss than the UiO-66 in this region, with more guest water molecules in the pores or OH groups due to the  $\text{-NH}_2$  and  $\text{-SO}_3\text{H}$  functional groups. In particular, the U-AS sample showed a slower weight drop than the U-A from 200 to 500 °C. This may be due to the oxidation of the pendant alkyl and  $\text{-SO}_3\text{H}$  groups in the U-AS. As the 2-aminoterephthalic acid or terephthalic acid was decomposed, the framework structure was disintegrated between 500 and 650 °C. U-A and U-AS showed less weight

loss than UiO-66. The framework of UiO-66 was completely decomposed before 600 °C, whereas the framework of U-A and U-AS was maintained even after 600 °C due to the presence of -NH<sub>2</sub> group, which is more stable in an N<sub>2</sub> condition.

## Experiment

The ion conductivity ( $\delta$ ) of membranes was obtained by dividing the area resistance of the membrane thickness from the area resistance values. The area resistance was measured without carbon-felt electrodes in the flowless single cell. The membrane is divided into two compartments with an effective area of 3.92 cm<sup>2</sup>. The two compartments were filled out fully with 2.25 ZnBr<sub>2</sub> + 0.5 M ZnCl<sub>2</sub>. The area resistance was evaluated with an electrochemical impedance analyzer (biologic potentiostat analyzer) at an amplitude of 10 mV in the frequency range of 1 Hz to 100 kHz. The area resistance was calculated by the formula below:

$$ASR = A \times (r_1 - r_2)$$

Where A is the effective area,  $r_1$  is the ohmic resistance of the cell with the membrane, and  $r_2$  is solution resistance without the membrane.

Ion transport numbers of membranes were measured by the liquid junction potential of the H-type with two Ag/AgCl reference electrodes filled with a 3 M NaCl. The left and right of the cell were filled with 0.01 M ZnBr<sub>2</sub> and 0.6 M ZnBr<sub>2</sub>, respectively. The Ag/AgCl electrodes were located in each cell. Using the measured open-circuit voltage (OCV) values derived from the difference in concentration of 0.01 M ZnBr<sub>2</sub> and 0.6 M ZnBr<sub>2</sub> electrolytes, the transference number was obtained by the following the Eq. (1) and (2)

$$E_j = \phi^\beta - \phi^\alpha = -\frac{RT}{F} \sum_i \int_\alpha^\beta \frac{t_i}{Z_i} d \ln a_i, \quad (1)$$

$$t_+ + t_- = 1, \quad (2)$$

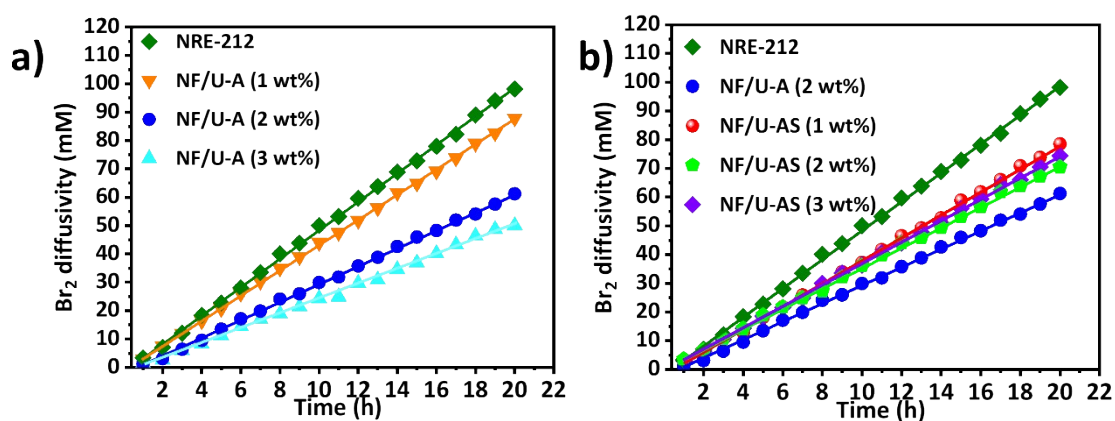

where,  $E_j$  means the liquid junction potential corresponding to OCV. R is the ideal gas constant.

T is the temperature. F is the Faraday constant.  $t_i$  is the ion transference number and  $z_i$  is the charge of the ion,  $a_i$  is the ion activity.  $\alpha$  and  $\beta$  are 0.01 M and 0.6 M ZnBr<sub>2</sub>, respectively.

To investigate the Zn plating behavior according to membranes, Zn symmetric cell was assembled in a 2032 coin cell with 14 mm of Zn metal foil (250  $\mu\text{m}$ ). 2 M ZnSO<sub>4</sub> was used as the electrolyte, and each membrane was stored in the 2 M ZnSO<sub>4</sub> for more than 24 hours before being applied to Zn symmetric coil cell. The cell was cycled at 1 mA h cm<sup>-2</sup> at 1 mA cm<sup>-2</sup>. After 5 cycles, Zn plating was performed for 1 mAh cm<sup>-2</sup>, and the morphology of Zn deposition was observed depending on membranes through SEM. Additionally, to demonstrate that membranes are capable of uniform Zn deposition, short-circuit time measurements were performed in a Zn symmetric cell. The short-circuit time was determined from the time required for the cell voltage to suddenly fluctuate at 1 mA cm<sup>-2</sup>.

## Optimization of U-A and U-AS amount depending on the membrane properties

**Fig. S24** The Br<sub>2</sub> diffusivity: a) NF/U-A membranes according to different U-A amounts and b) NF/U-AS membranes according to different U-AS amounts. The NRE-212 membrane was used for comparison.

To optimize the U-A and U-AS content in the polymer matrix as a composite membrane, membrane properties were investigated according to U-A and U-AS amount, respectively. The U-A and U-AS contents of 1.0, 2.0, and 3.0 wt% were introduced based on the weight of the Nafion membrane not containing any additive.

First, the Br<sub>2</sub> diffusivity was measured at different times to confirm the Br<sub>2</sub> crossover through the membrane (Fig. S24). In the case of optimization for U-A content, as the U-A content increased, a greater amount of Br<sub>2</sub> was captured, demonstrating lower Br<sub>2</sub> diffusivity (Fig. S21a). As a result, the NF/U-A (3 wt%) exhibited the lowest Br<sub>2</sub> crossover property. The NF/U-AS membranes indicated low Br<sub>2</sub> diffusivity in the order of NF/U-AS 1 wt% < NF/U-AS 2

wt% and NF/U-AS 3 wt% (Fig. S24b). However, no significant differences were found in Br<sub>2</sub> diffusivity of NF/U-AS membranes depending on the U-AS amount introduced. As the U-AS content in the U-AS-based membrane varies, the sulfonic group on the surface of the U-AS also becomes different, not following the same trend as U-A based membranes.

In addition to Br<sub>2</sub> diffusivity, the membrane properties such as area-specific resistance (ASR), ion conductivity, the concentration at which Br<sub>2</sub> crossover occurred based on 12 hours, water uptake and contact angle are summarized in Table S4. The NF/U-A 3 wt% membrane had the lowest ion conductivity as a high amount of the U-A interacted with the sulfonic group of Nafion. Even though the NF/U-AS membranes were introduced into the Nafion matrix, they maintained ion conductivity as the NF/U-AS did not suffer the loss of the ion-conducting group due to the functionalization of the sulfonate group on U-AS. In particular, NF/U-AS (2 wt%) was determined to be the optimal amount based on appropriate ionic conductivity, high hydrophilicity of the surface, large electrolyte absorption ability, and low crossover property. NF/U-A was also determined to be 2 wt%, which has the most suitable properties among NF/U-A membranes with a content of 1 to 3 wt%. Based on the results, NF/U-A (2 wt%) and NF/U-AS (2 wt%) were referred to as NF/U-A and NF/U-AS, respectively, and the battery performances with the comparison of membrane characteristics were dealt with in the main script.

**Table S4.** Summary of membrane properties for NF/U-A and NF/U-AS membranes depending on the additive amount

Membranes	Water uptake (%)	Contact angle (°)	Ion conductivity (mS cm <sup>-1</sup> )	Br <sub>2</sub> concentration at 12 h (10 mM L <sup>-1</sup> )
NRE-212	24.20	58.55	12.37	59.67
NF/U-A (1 wt%)	23.01	65.27	7.85	51.80
NF/U-A (2 wt%)	21.86	67.67	3.38	35.79
NF/U-A (3 wt%)	22.45	76.07	2.45	29.75
NF/U-AS (1 wt%)	32.14	35.98	12.29	46.63
NF/U-AS (2 wt%)	34.12	31.21	12.21	44.05
NF/U-AS (3 wt%)	35.87	23.40	12.12	44.05
