## Text S1 Reagents and Materials

Polystyrene resin (PS) was provided by Xi'an Jinwotai Environmental Protection Technology Co., Ltd. (Xi'an, China). Chloroform ( $\text{CHCl}_3$ ), urea, concentrated nitric acid (68%  $\text{HNO}_3$ ), concentrated sulfuric acid (98%  $\text{H}_2\text{SO}_4$ ), concentrated hydrochloric acid (36%  $\text{HCl}$ ), sodium hydroxide ( $\text{NaOH}$ ), and stannous chloride ( $\text{SnCl}_2$ ) were purchased from Sichuan Xilong Science Co., Ltd. (Chengdu, China). Ethanol, Ammonium Hydroxide (28%  $\text{NH}_3 \cdot \text{H}_2\text{O}$ ), ferrous chloride tetrahydrate ( $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ ), hexahydrate ferric chloride ( $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ ), and tetracycline (TC) were supplied by Anhui Zesheng Technology Co., Ltd. (Anqing, China). Argon was purchased from Lanzhou Hongli Gas Co., Ltd. (Lanzhou, China). Deionized water was homemade for the laboratory.

## Text S2 Synthesis of APS

First, weighed 6 g of polystyrene resin (PS) and soaked them in 50 mL chloroform to swell. Filtered by suction to remove the solvent, 0.27 g of urea was added (to eliminate by-products) and then transferred to a 100 mL four-necked flask. Slowly added 11 mL of mixed acid composed of 10.5 mL 60% concentrated nitric acid and 22.5 mL concentrated sulfuric acid cooled with ice water, and then started stirring. The remaining mixed acid was slowly dropped within 1h, and the reaction temperature was controlled below 50 °C. The reaction was refluxed and stirred at 65–70 °C for 3 h. After the reaction was completed, cooled to room temperature, carefully poured the reactants into ice water, filtered, rinsed with water to neutral, and dried to obtain golden nitrified PS (NPS) (Fig. S1).

4.05 g of NPS was placed in a 250 mL round-bottom flask with 48 g of tin dichloride, 54 mL of concentrated hydrochloric acid, and 60 mL of absolute ethanol; and then refluxed in a boiling water bath for 10 h. At the end of reflux, the supernatant was discarded by pouring and the resin was washed with excess 2 mol/L  $\text{NaOH}$  solution until no white precipitate precipitated. The resin was then washed

with 2 mol/L HCl solution and finally washed to neutrality with deionized water. The khaki aminated PS (APS) was obtained by vacuum drying at 60 °C for 12 h.

### Text S3 Tauc Plot method

Most of the valence band (VB) electrons and conduction band (CB) electrons of semiconductors are distributed near the forbidden band, so when the photon energy is close to the width of the bandgap, a large number of electrons can transition by absorbing photon energy, and the absorption coefficient increases with increased the number of photons.

For semiconductor materials, the relationship between optical band gap and absorption coefficient is as follows:<sup>1</sup>

$$(\alpha h\nu)^{1/n} = \lambda(h\nu - E_g)$$

where  $\alpha$  is the absorption coefficient,  $h\nu$  is the photon energy,  $h$  is the Planck constant,  $\nu$  is the incident photon frequency,  $\lambda$  is the proportional constant, and  $E_g$  is the band gap width of semiconductor materials. The n value is related to the type of semiconductor material. When the semiconductor material is a direct band gap, the n value is 1/2; when the semiconductor material is an indirect band gap, the n value is 2.

**Table S1** the mass of PANI/Fe<sub>3</sub>O<sub>4</sub>/APS compared to APS before and after the two loadings.

Samples	1	2	3
APS (g)	1.6526	2.0561	1.8453
