## Methodology

**Quantum calculations.** Spin-polarized density function theory (DFT)<sup>1, 2</sup> calculations were performed using the DMol<sup>3</sup> package. A generalized gradient approximation (GGA)<sup>3, 4</sup> in the form of revised-Perdew-Burke-Ernzerhof (RPBE) functional<sup>5</sup> was utilized to account for the exchange-correlation interaction, accompanied by the DFT-D2<sup>6</sup> semi-empirical method to estimate the dispersion correction. The DFT semi-core pseudopotential (DSPP) method<sup>7</sup> for the numeric atomic orbital basis set was implemented to treat the core electron interactions. A  $\Gamma$ -centered k-point grid of  $4 \times 4 \times 1$  was employed to sample the Brillouin zone in structural relaxation, while an  $8 \times 8 \times 1$  k-point mesh was used for electronic properties calculations. The convergence tolerances of energy, force, and displacement for geometry optimization were set as  $1.0 \times 10^{-6}$  Ha,  $1.0 \times 10^{-3}$  Ha/Å, and  $5.0 \times 10^{-3}$  Å, respectively. The Gaussian smearing with a smearing width of  $5.0 \times 10^{-3}$  Ha was used to accelerate the convergence. The distance of vacuum layer in the z-direction was set to 20 Å to eliminate the interactions between periodic regions. Ab initio molecular dynamics (AIMD) simulations with NVT ensemble were conducted to evaluate the dynamic stability.

The minimum energy paths (MEP) were determined by the linear synchronous transit/quadratic synchronous transit (LST/QST) methods<sup>8</sup> with a root mean squared (RMS) convergence of  $1.0 \times 10^{-3}$  Ha/Å and further confirmed by the nudged elastic band (NEB) method<sup>9</sup>. The reaction Gibbs free energy change ( $\Delta G$ ) of the elementary steps was constructed based on the computational hydrogen electrode (CHE) theory developed by Nørskov et al.<sup>10</sup>, where the chemical potential of  $(H^+ + e^-)$  pair in solution was equal to the half of the chemical potential of a gas-phase H<sub>2</sub> and the reference potential was set to reversible hydrogen electrode (RHE). The corresponding  $\Delta G$  can be calculated by

$$\Delta G = \Delta E + \Delta ZPE - T\Delta S$$

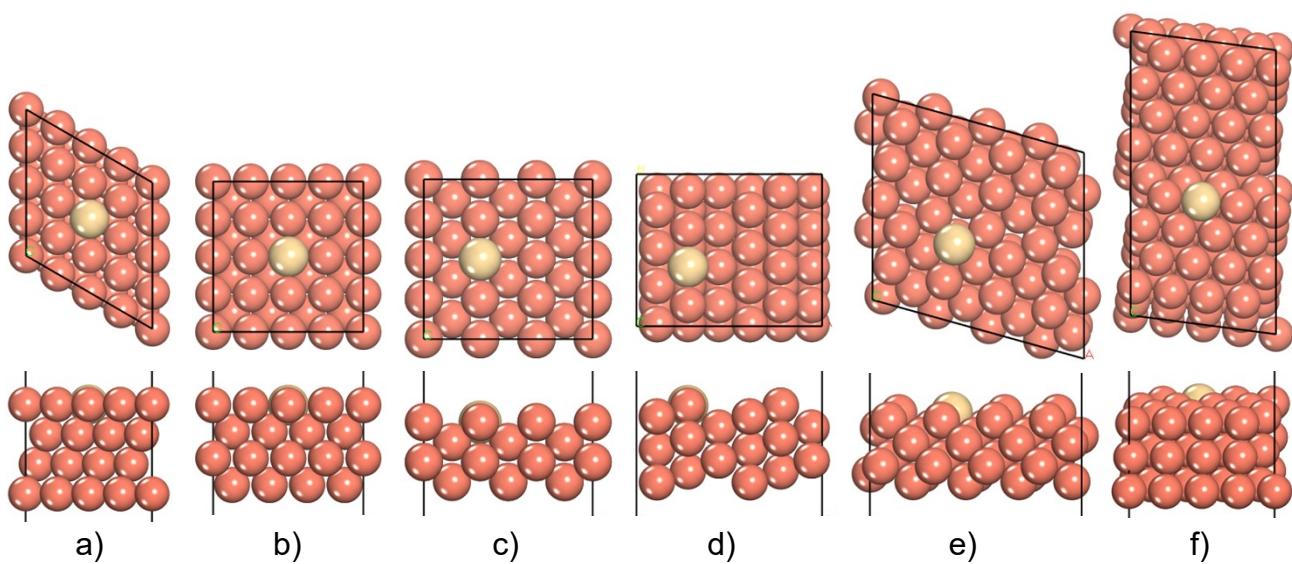

where  $\Delta E$  is the total DFT energy,  $\Delta ZPE$  and  $\Delta S$  are the contributions of zero point energy and entropy to the  $\Delta G$ . In this study, the temperature  $T$  is 298.15 K. The limiting potential ( $U_L$ ) was defined as  $U_L = -\Delta G_{\max}/e$ , where  $\Delta G_{\max}$  is the free energy change of potential limiting step (PLS).

**Machine learning (ML).** The ML scheme of homemade code was accomplished within Numpy<sup>11</sup>, Pandas<sup>12</sup>, Scikit-learn<sup>13</sup>, and XGBoost<sup>14</sup> packages, as performed in the Python3 environment. Five state-of-the-art ML algorithms, namely, Support Vector Regression (SVR)<sup>15</sup>, Kernel ridge regression (KRR)<sup>16</sup>, Least Absolute Shrinkage and Selection Operator Regression (LASSO)<sup>17</sup>, Random Forest Regression (RFR)<sup>18, 19</sup>, and eXtreme Gradient Boosting Regression (XGBoost)<sup>14</sup> were employed to build the ML models. With the aid of the Optuna<sup>20</sup>, the optimal hyper-parameters were successfully searched, as available in **Table S12**. Taking the XGBoost model as an example, the `n_estimators`, `max_depth`, `min_child_weight`, `learning_rate`, `colsample_bytree`, `subsample`, `reg_alpha`, `reg_lambda` and `gamma` were considered to seek the optimal hyper-parameters using Optuna algorithm.

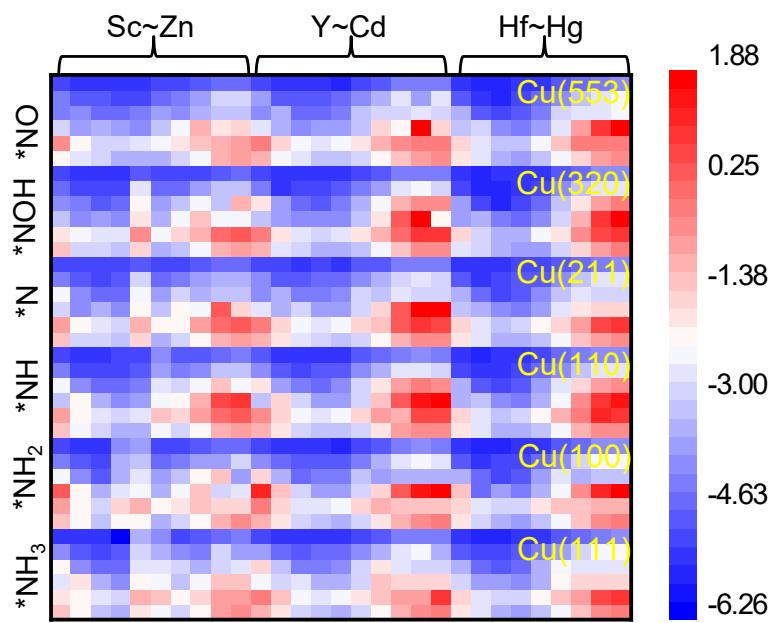

After normalization pre-processing<sup>21</sup>, the raw data calculated by DFT were randomly shuffled and divided into train and test sets with the ratio of 4 : 1. To avoid the risk of over-fitting, 10-fold cross validation<sup>22</sup> was executed in the process of training ML model. The values of the coefficients of determination ( $R^2$ ) and root mean square error (RMSE) were utilized to estimate the errors of five algorithms, in which  $R^2$  represents the proportion of variance that has been parsed by the independent variables in the corresponding model, while RMSE stands for the differences between the ML-predicted and DFT-calculated results. That is, a ML model endowed with better generalization ability corresponds to a smaller RMSE and larger  $R^2$ . In addition, the SHapley

Additive exPlanation (SHAP)<sup>23-25</sup> was adopted to elucidate the output of the ML models. Based on the optimal ML model, the algorithm of SHAP was used to calculate the importance of input features.

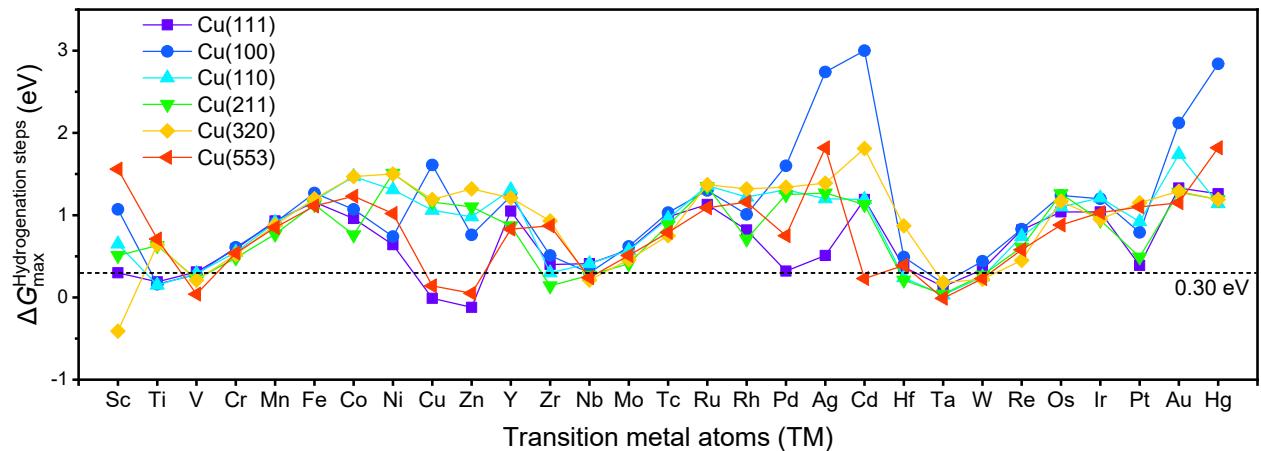

Based on the optimized adsorption configurations via DFT method, the many-body tensor representation (MBTR)<sup>26</sup> was adopted to encode the structure through the Dscribe 2.1.0<sup>27</sup>. As given in **Table S13**, the parameters were used to perform the calculation of MBTR. Then, the principal component analysis (PCA) was used to decrease the dimensionality of the dataset generated by MBTR, reducing the dimensionality to 6 and combined these data with  $Z$ ,  $X$ ,  $N$ ,  $N_d$ ,  $I_1$  and  $R_d$  as dataset for subsequent ML.
