Corresponding forward propagation formula of the deep learning models.

The Graph Convolutional Layer (GCN)¹ can be interpreted as a type of "convolution operation" over graph structures. The formula for graph convolution is given as:

$$h_i^{(l+1)} = \sigma \left(b^{(l)} + \sum_{j \in N(i)} \frac{1}{c_{ji}} h_j^{(l)} W^l \right) \#S1$$

where $N(i)$ represents the set of neighbors of node i , c_{ji} is the normalization factor calculated as the square root product of the node degrees, σ refers to the activation function of the convolutional layer, $h_j^{(l)}$ represents the l -th hidden layer feature of neighboring nodes, and $W^{(l)}$ is the learnable weight matrix. For graphs with edge features, the graph convolution incorporates the edge weight e_{ij} , as described by the following formula:

$$h_i^{(l+1)} = \sigma \left(b^{(l)} + \sum_{j \in N(i)} \frac{e_{ji}}{c_{ji}} h_j^{(l)} W^l \right) \#S2$$

In Graph Attention Networks (GAT)², the core of the graph convolution lies in its attention mechanism, which calculates the similarity between each node and its neighbors to assign different attention weights. These weights are then combined with the node's eigenvectors to derive an updated representation of the node. The update rules for the graph attention layer can be expressed as:

$$h_i^{(l+1)} = \sum_{j \in N(i)} \alpha_{i,j} W^{(l)} h_j^{(l)} \#S3$$

where $\alpha_{i,j}$ represents the attention score between node i and node j , and $W^{(l)}$ is the learnable weight matrix. Similarly, in order to incorporate edge features into the node features of the graph attention mechanism, Kamiński et al.³ define edge feature aggregation as follows:

$$e_{ij} = \tilde{F}(f'_{ij}) \#S4$$

$$f'_{ij} = \text{LeakyReLU}(A[h_i \| f_{ij} \| h_j]) \#S5$$

Here, f'_{ij} refers to the edge feature, A is the weight matrix, \vec{F} represents the weight vector, and \parallel denotes concatenation. After aggregating the edge features, the node features are generated and updated using the conventional GAT method.

The Graph Isomorphism Network (GIN)⁴ aggregates the representations of neighboring nodes through summation. The convolution operator formula⁴ for GIN is as follows:

$$h_i^{(l+1)} = f_{\theta}((1 + \epsilon)h_i^l + \text{aggregate}(\{h_j^l, j \in N(i)\})) \quad \#S6$$

where $\text{aggregate}(\cdot)$ represents the aggregation operation, which can be selected from options such as "sum," "max," or "mean." The ϵ value is a constant that can be added. Graph isomorphic networks that incorporate edge features⁵ can be described by the following equation:

$$h_i^{(l+1)} = f_{\theta}\left((1 + \epsilon)h_i^l + \sum_{j \in N(i)} \text{ReLU}(h_j^l + e_{j,i}^l)\right) \quad \#S7$$

In Message Passing Neural Networks (MPNN)⁶, a neural network encodes the characteristic information of the node itself and its neighbors. The formula is as follows:

$$h_i^{(l+1)} = h_i^l + \text{aggregate}(\{f_{\theta}(e_{ij}) \cdot h_j^l, j \in N(i)\}) \quad \#S8$$

The interaction layer to simulate donor-acceptor interactions⁷ as follows:

$$I_r = \tanh(F_{don}F_{acc}D_r)W_r \quad \#S9$$

Where r represents the r -th space bucket. D_r is the distance, W_r is the weight information output of the distance self-feedback module, and F_{don} and F_{acc} are the embedding features of the donor and the acceptor, respectively.

In general, the choice of convolution operator can significantly affect performance on different tasks due to the varying aggregation methods used for neighboring nodes. Therefore, it is essential to analyze the task at hand and determine which aggregation method best aligns with the specific characteristics of the task or objective.
