**Fig. S6** Dependence of photocurrent density produced by ITO/(GO/Ru4)<sub>1</sub> film on the concentrations of the electron donor hydroquinone in 0.1 M Na<sub>2</sub>SO<sub>4</sub> at an applied potential of -0.2 V versus SCE upon irradiation with 100 mW/cm<sup>2</sup> white light.

**Fig. S7** Dependence of photocurrent density produced by ITO/(GO/Ru4)<sub>1</sub> film on the concentrations of the electron acceptor K<sub>3</sub>Fe(CN)<sub>6</sub> in 0.1 M Na<sub>2</sub>SO<sub>4</sub> at an applied potential of -0.2 V versus SCE upon irradiation with 100 mW/cm<sup>2</sup> white light.

**Fig. S8** Photocurrent density changes induced by switching on and off the irradiation of ITO/(GO/Ru4)<sub>1</sub> film. The measurement was carried out at the potential of -0.2 V versus SCE in 0.1 M (a) air-equilibrated Na<sub>2</sub>SO<sub>4</sub> aqueous solution and (b) degassed Na<sub>2</sub>SO<sub>4</sub> aqueous solution by bubbling nitrogen for 10 min into the electrolyte solution.

**Fig. S9.** (a) Photocurrent changes induced by turning the irradiation on and off of ITO/(GO/Ru4)<sub>n</sub> (n = 1-6) films that were biased at -0.2 V vs. SCE. (b) Dependence of photocurrents of ITO/(GO/Ru4)<sub>n</sub> (n = 1-6) films on the number of layers.

**Fig. S10** Comparison of visible absorption spectra (solid line) with the photocurrent action spectrum (square) of ITO/(GO/Ru4)<sub>4</sub> film.

### Preparation of the multilayer films

The thin film fabrication procedures are schematically illustrated in Fig. 2. The quartz or ITO substrates were cleaned sequentially by sonication in detergent, washing with copious water, and soaking in Piranha solution (v/v 3:1, concentrated H<sub>2</sub>SO<sub>4</sub>/30% H<sub>2</sub>O<sub>2</sub>) for the glass substrate or a mixed solution (v/v/v 1:1:5, 25% NH<sub>3</sub>·H<sub>2</sub>O/30% H<sub>2</sub>O<sub>2</sub>/DI water) for 40 min. *Piranha solution is highly corrosive and powerful oxidizing agent. It should be handled with extreme caution in order to avoid inhalation and contacts with skin and eyes.* After the cleaned substrates were then subjected to following treatments: (I) silanization with a 3-aminopropyltriethoxysilane/ethanol (5:95, v/v) solution for 12 h at room temperature made the surface of the substrate covered with the amino groups. (II) The amino covered substrates were protonated by contacting with an aqueous HCl solution (pH ≈ 3) for 10 min. (III) The protonated substrates were immersed into a 1 mg/mL GO aqueous solution for 15 min, and were washed carefully with ethanol and DI water, produced the substrates covered with negatively charged GO on the surface. (IV) The GO deposited substrates were immersed in a 0.5 mM **Ru4**(ClO<sub>4</sub>)<sub>2</sub> aqueous solution for 15 min, and were rinsed with ethanol and DI water carefully, and air-blow dried. Repetition of steps III and IV for *n* times afforded the multilayer films (GO/**Ru4**)<sub>*n*</sub> on the both sides of the substrates.
